## What is Artificial Intelligence?

---

At its core, **Artificial Intelligence (AI)** is the science of building machines that can perform tasks that typically require human intelligence — things like recognizing speech, making decisions, translating languages, or writing code.

The field sits at the intersection of mathematics, computer science, statistics, and cognitive science.

### The AI Hierarchy

AI is often described as a set of nested disciplines:

## A Brief History of AI

---

AI has gone through several waves of excitement and disappointment (called “**AI winters**”) before the current explosion.

### Key Milestones

- |                  |                                                                                          |
|------------------|------------------------------------------------------------------------------------------|
| <b>1950</b>      | Alan Turing proposes the Turing Test as a measure of machine intelligence.               |
| <b>1956</b>      | The Dartmouth Conference coins the term “Artificial Intelligence” — the field is born.   |
| <b>1970s–80s</b> | <i>First AI Winter</i> : over-promised results lead to funding cuts and disillusionment. |
| <b>1980s</b>     | Expert systems rise — rule-based programs dominate industrial AI applications.           |
| <b>1987–93</b>   | <i>Second AI Winter</i> : expert systems prove brittle; investment collapses again.      |
| <b>1997</b>      | IBM’s Deep Blue defeats world chess champion Garry Kasparov.                             |
| <b>2012</b>      | AlexNet wins ImageNet by a wide margin — the deep learning era begins.                   |
| <b>2016</b>      | DeepMind’s AlphaGo defeats world Go champion Lee Sedol.                                  |
| <b>2017</b>      | Google publishes “ <i>Attention Is All You Need</i> ” — the Transformer is born.         |

- 2020** GPT-3 demonstrates few-shot learning; generative AI enters the mainstream.
- 2022+** ChatGPT launches; AI becomes a mass-market technology.

## Types of AI

### By Capability

#### Narrow AI (ANI) — exists today

Performs one specific task extremely well: chess, image recognition, language. Every AI product you use is narrow AI.

#### General AI (AGI) — hypothetical

A system that can do any intellectual task a human can. Does not yet exist. Researchers disagree on how far away it is.

#### Superintelligence (ASI) — hypothetical

An AI far surpassing human intelligence across all domains. A topic of intense philosophical and safety debate.

### By Learning Approach

| Approach                        | How it works                                | Examples                                               |
|---------------------------------|---------------------------------------------|--------------------------------------------------------|
| <b>Supervised Learning</b>      | Learns from labeled input-output pairs      | Spam filter, image classifier, price predictor         |
| <b>Unsupervised Learning</b>    | Finds hidden patterns in unlabeled data     | Customer clustering, anomaly detection, topic modeling |
| <b>Reinforcement Learning</b>   | Learns via trial, error, and reward signals | AlphaGo, robot locomotion, ChatGPT (RLHF)              |
| <b>Self-Supervised Learning</b> | Generates its own labels from raw data      | GPT, Claude, BERT, CLIP                                |

## Neural Networks and Deep Learning

The revolution in modern AI came from **artificial neural networks** — systems loosely inspired by the human brain.

### How a Neuron Works

Each artificial neuron computes:

$$y = f\left(\sum_{i=1}^n w_i x_i + b\right)$$

where  $x_i$  are inputs,  $w_i$  are learned weights,  $b$  is a bias term, and  $f$  is an **activation function** (e.g. ReLU, sigmoid, tanh).

## Network Architecture

A neural network consists of stacked **layers**:

- **Input layer** — receives raw features (pixels, token embeddings, numerical values)
- **Hidden layers** — progressively extract more abstract representations
- **Output layer** — produces the final prediction or classification

**Deep Learning** simply means using many hidden layers. A deep image classifier might learn:

edges  $\rightarrow$  textures  $\rightarrow$  parts  $\rightarrow$  objects

## Training: Backpropagation and Gradient Descent

Training a neural network means finding the weights  $\mathbf{w}$  that minimize a **loss function**  $\mathcal{L}$ . This is done via **gradient descent**:

$$\mathbf{w} \leftarrow \mathbf{w} - \eta \nabla_{\mathbf{w}} \mathcal{L}$$

where  $\eta$  is the **learning rate**. **Backpropagation** computes  $\nabla_{\mathbf{w}} \mathcal{L}$  efficiently using the chain rule of calculus.

## Key Architectures

**CNNs (Convolutional Neural Networks)** Specialized for images. Use sliding filter kernels.

**RNNs / LSTMs** Process sequential data. Largely superseded by Transformers.

**Transformers** Attention-based architecture. State of the art for language, vision, and multi-modal tasks.

**Diffusion Models** Learn to denoise data; used in image and video generation.

**GANs** Two networks (generator + discriminator) compete to produce realistic outputs.

## The Transformer Revolution

---

The 2017 paper “*Attention Is All You Need*” (Vaswani et al.) introduced the **Transformer** — the foundation of almost every powerful AI system today.

### Self-Attention

The key innovation is **self-attention**: every token can attend to every other token with a learned weight. For a sequence of tokens  $x_1, \dots, x_n$ , each token  $x_q$  (the *query*) computes attention scores against all keys  $x_k$ :

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^\top}{\sqrt{d_k}}\right)V$$

where  $Q, K, V$  are learned projections of the input, and  $d_k$  is the key dimension.

## Why Attention Matters

Consider the sentence: *"I went to the bank to get money."*

The word *bank* could mean a riverbank or a financial institution. Self-attention allows the model to assign a high weight to *money*, resolving the ambiguity — without any hand-coded rules.

## Large Language Models (LLMs)

LLMs are Transformers pre-trained on massive text corpora using **self-supervised learning**: the model predicts the next token given all previous tokens. After pre-training they are fine-tuned with **RLHF** (Reinforcement Learning from Human Feedback) to follow instructions and behave helpfully.

Notable LLMs: GPT-4, Claude, Gemini, Llama, Mistral.

## AI Applications Across Industries

| Domain         | Key Applications                                                                                                   |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| Healthcare     | Medical imaging diagnostics, drug discovery, protein structure prediction (AlphaFold), clinical note summarization |
| Finance        | Fraud detection, algorithmic trading, credit scoring, risk modeling, robo-advisors                                 |
| Transportation | Self-driving vehicles, traffic flow optimization, route planning, predictive maintenance                           |
| Education      | Personalized tutoring, automated grading, adaptive curricula, language learning apps                               |
| Creative Arts  | Image generation (DALL·E, Midjourney), music composition, video synthesis, writing assistance                      |
| Environment    | Climate modeling, smart energy grids, wildlife monitoring, precision agriculture                                   |
| Software Dev   | Code generation (GitHub Copilot, Claude Code), bug detection, automated testing, documentation                     |
| Cybersecurity  | Threat detection, intrusion prevention, deepfake identification, biometric authentication                          |

## Ethics, Safety, and the Future of AI

### Bias and Fairness

AI systems trained on biased data reproduce and amplify those biases. A hiring algorithm trained on historical data may discriminate against women. Facial recognition systems have shown significantly higher error rates on darker skin tones.

## Alignment

As AI becomes more capable, ensuring it does what humans *actually* want — not just what they literally say — becomes critical. This is the core problem of **AI alignment** research at organizations such as Anthropic, DeepMind, and OpenAI.

## Job Displacement

AI automates cognitive tasks at scale. This creates economic disruption but also new opportunities — the historical pattern with every major technological revolution.

## Deepfakes and Misinformation

Generative AI makes it trivially easy to fabricate realistic audio, video, and text attributed to real people, posing serious risks to public trust and democratic processes.

## Privacy

AI systems consume vast amounts of personal data, raising questions about surveillance, consent, and data sovereignty.

## Existential Risk

A serious community of researchers studies the long-term risks of systems that might eventually surpass human capabilities across all domains, and the difficulty of maintaining meaningful human oversight over such systems.

### Anthropic's approach: Constitutional AI

Anthropic (the company behind Claude) pursues **Constitutional AI** — a method that trains models to be helpful, harmless, and honest by having the model critique and revise its own outputs according to a set of principles, combined with RLHF.

## Key Concepts Glossary

| Term                      | Definition                                                                                       |
|---------------------------|--------------------------------------------------------------------------------------------------|
| <b>Parameter</b>          | A learned weight in a neural network. GPT-4 has ~1.8 trillion parameters.                        |
| <b>Training</b>           | The process of adjusting weights using data and an optimization algorithm.                       |
| <b>Inference</b>          | Running a trained model to make predictions on new inputs.                                       |
| <b>Overfitting</b>        | When a model memorizes training data but fails to generalize to new data.                        |
| <b>Gradient descent</b>   | The optimization algorithm that trains neural networks by minimizing loss.                       |
| <b>Backpropagation</b>    | Algorithm that computes weight gradients via the chain rule.                                     |
| <b>Embedding</b>          | A dense numerical vector representing a word, image, or concept in latent space.                 |
| <b>Hallucination</b>      | When an LLM confidently generates plausible but factually incorrect content.                     |
| <b>Fine-tuning</b>        | Adapting a pre-trained model to a specific downstream task.                                      |
| <b>RLHF</b>               | Reinforcement Learning from Human Feedback — the key alignment technique for ChatGPT and Claude. |
| <b>Prompt engineering</b> | Crafting inputs strategically to elicit better outputs from LLMs.                                |
| <b>RAG</b>                | Retrieval-Augmented Generation — grounding LLMs with external knowledge sources.                 |
| <b>Multimodal AI</b>      | AI that processes multiple data modalities simultaneously (text + images + audio).               |
| <b>Agent</b>              | An AI system that can take actions, use tools, and pursue goals autonomously.                    |
| <b>Token</b>              | The basic unit of text processed by an LLM; roughly 0.75 words on average.                       |
| <b>Context window</b>     | The maximum number of tokens an LLM can process at once.                                         |

## Learning Paths

## The Math Path

Linear algebra → Calculus → Probability & statistics → Information theory → Convex optimization

*Key texts:* *Mathematics for Machine Learning* (Deisenroth et al.), *Pattern Recognition and Machine Learning* (Bishop).

## The Coding Path

Python → NumPy / Pandas → Scikit-learn → PyTorch or TensorFlow → Hugging Face Transformers

*Key resources:* fast.ai, *Hands-On Machine Learning* (Géron), PyTorch tutorials.

## LLMs Deep Dive

Tokenization → Transformer architecture → Pre-training → RLHF → Prompt engineering → Agents & tool use

*Key papers:* “Attention Is All You Need” (2017), “Language Models are Few-Shot Learners” (2020), “Constitutional AI” (2022).

## Ethics and Safety Path

Algorithmic bias → Fairness metrics → AI alignment → AI safety research → Governance & policy

*Key resources:* AI Now Institute, Center for AI Safety, *The Alignment Problem* (Christian).

## Generative AI Path

GANs → Variational Autoencoders → Diffusion models → Multimodal models → Video generation

*Key papers:* “Denoising Diffusion Probabilistic Models” (2020), “CLIP” (2021), “Sora” technical report (2024).
